Recommendations	Class <sup>a</sup>	Level <sup>b</sup>
Immediate PCI is indicated for patients with cardiogenic shock if coronary anatomy is suitable. If coronary anatomy is not suitable for PCI, or PCI has failed, emergency CABG is recommended. <sup>248</sup>	I option même partielle	B
Invasive blood pressure monitoring with an arterial line is recommended.	I	C
Immediate Doppler echocardiography is indicated to assess ventricular and valvular functions, loading conditions, and to detect mechanical complications.	I option est interdite	C
It is indicated that mechanical complications are treated as early as possible after discussion by the Heart Team.	I	C

more frequent in the posteromedial papillary muscle because of its single artery blood supply.<sup>53,54</sup> Papillary muscle rupture usually presents as sudden haemodynamic deterioration with acute dyspnoea, pulmonary oedema, and/or cardiogenic shock. A systolic murmur is frequently underappreciated. Emergency echocardiography is diagnostic. Immediate treatment is based on afterload reduction to reduce regurgitant volume and pulmonary congestion. Intravenous diuretic and vasodilator/inotropic support, as well as IABP, may stabilize patients in preparation for angiography and surgery. Emergency surgery is the treatment of choice although it carries a high operative mortality (20–25%). Valve replacement is often required, but cases of successful repair by papillary muscle suture have been increasingly reported and appear to be a better option in experienced hands.<sup>55</sup>

### Comparison of the Efficacy of ECMO With

## Conclusion

This study showed that ECMO combined with IABP could be more effective in improving survival in patients with CS than ECMO alone.

**Objective:** Studies on extracorporeal membrane oxygenation (ECMO) with and without an intra-aortic balloon pump (IABP) for cardiogenic shock (CS) have been published, but there have been no meta-analyses that compare

Prognosis of patients with cardiogenic shock or after cardiac arrest substantially lower high mortality. Therefore, all hope is pinned like intra-aortic balloon pump (IABP), venoarterial extracorporeal and others (1–4). The Extracorporeal Life Support (ECLS) Or

# PCI ? CABG ?

COR	LOE	RECOMMENDATIONS
1	A	1. In patients with STEMI and ischemic symptoms for <12 hours, PCI should be performed to improve survival (1-5).
1	B-R	2. In patients with STEMI and cardiogenic shock or hemodynamic instability, PCI or CABG (when PCI is not feasible) is indicated to improve survival, irrespective of the time delay from MI onset (6,7).
1	B-NR	3. In patients with STEMI who have mechanical complications (e.g., ventricular septal rupture, mitral valve insufficiency because of papillary muscle infarction or rupture, or free wall rupture), CABG is recommended at the time of surgery, with the goal of improving survival (8,9).
2a	B-ii	4. In patients with STEMI and evidence of failed reperfusion after fibrinolytic therapy, rescue PCI of the infarct artery should be performed to improve clinical outcomes (10-13).
5. In patients with STEMI who are treated with fibrinolytic therapy, angiography within 3 to 24 hours with the intent to perform PCI is reasonable to improve clinical outcomes (14-20).		

mechanical complications.

It is indicated that mechanical complications are treated as early as possible after discussion by the Heart Team.
